SLAC April 30-May 2, 2001

# OUTLINE

- Introduction
- Physics motivations
- Detector Requirements
- Detector Layout
- Conclusions

# Physics Motivations

- R measurement
  - evolution of  $\alpha_{EM}$
  - hadronic contribution to  $g_{\mu-2}$
- Nucleon form factors
- Other baryon form factors
- Meson form factors
- Vector meson spectroscopy
- Multihadron channels
- $\gamma\gamma^*$  interactions

# R measurements at low energy

Precision Tests of the EW Gauge Theory, ICHEP2000, Osaka. A. Gurtai

Global Fit to EW data

## Ratio between neutron and proton form factors

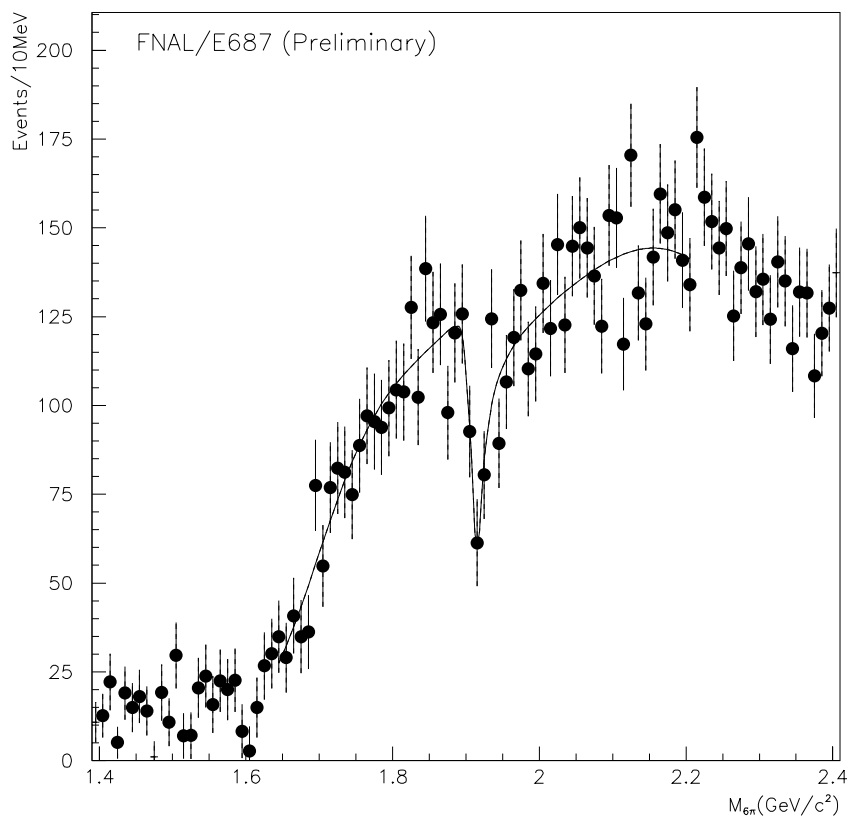

Data obtained primarily by the FENICE experiment (Adone, Frascati).  $\int Ldt = 0.4 \text{ pb}^{-1}$  80 events.

**The neutron form factor is bigger than that of the proton !!!**

Assumes  $G_E = G_M$  near threshold for both proton and neutron. New, high-statistics measurement needed to separate electric and magnetic form factors.

DM2 data

FNAL E687

$3\pi^+3\pi^-$  inv. mass distribution in high energy photoproduction

## Experimental Requirements

- For the measurement of **R** one would want ideally a **hermetic detector**. Hadronic events can be defined **inclusively** by requiring a **minimum number of particles within the detector acceptance**, e.g.:
  - 3 charged particles, or
  - 2 charged particles and 1  $\gamma$  at large angle, or
  - 1 charged particles and 2  $\gamma$  reconstructing a  $\pi^0$ .

Potentially large systematic errors associated with calculation of overall acceptance.

Reconstruct the event completely and measure the cross section of each individual channel contributing to **R**.

- The study of **exclusive final states** (e.g. vector meson spectroscopy, multihadronic channels) will also require the ability to **reconstruct the event completely**.
- The study of **nucleon form factors** requires the **additional capability to detect neutrons and antineutrons**.

# Detector Requirements

- low mass tracking
- momentum measurement with good precision
- EM calorimetry
- luminosity measurement
- N  $\bar{N}$  detector
- particle ID
- modest cost

## Some important characteristics

- magnet: 0.1-0.3 T vertical B field (must NOT disturb LER and HER)
- The contribution of multiple scattering to the momentum resolution as high as 2 %.
- $\beta_{cm} \approx 0.8$
- event rate: < 1 Hz

$$e^+e^- \rightarrow \text{hadrons}$$

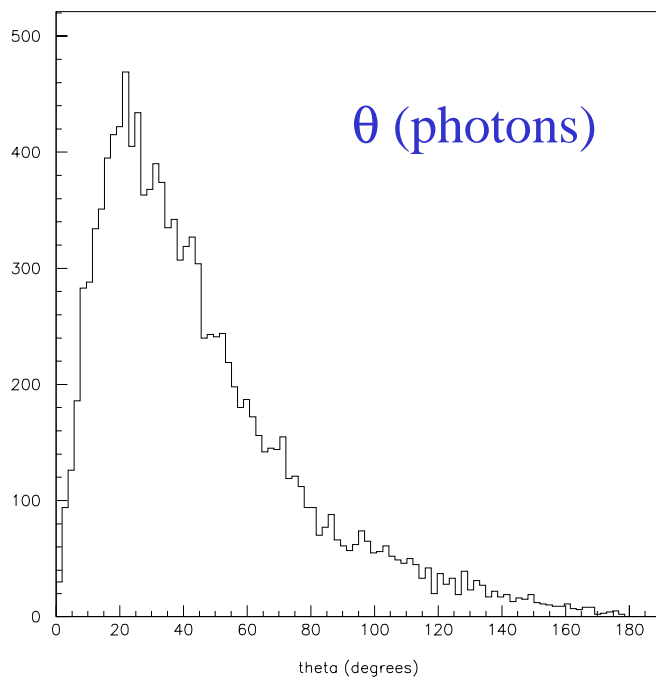

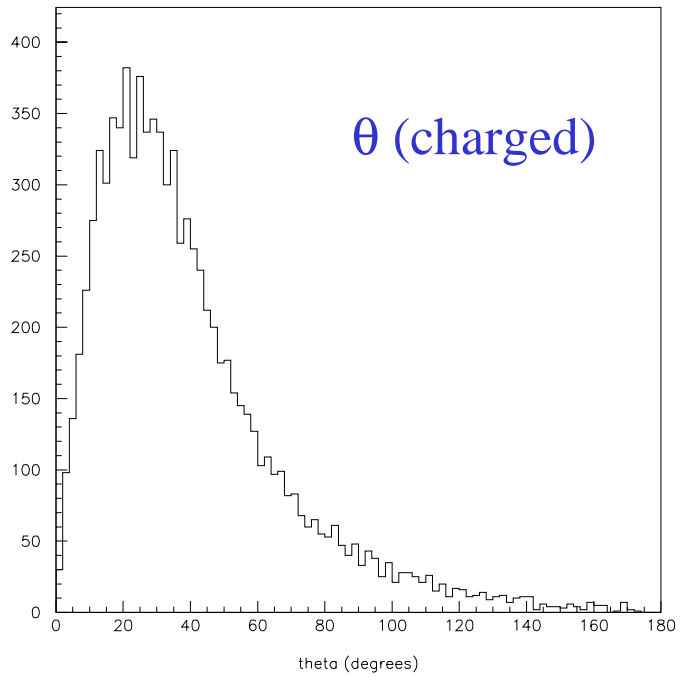

## Photon energy distribution

Full efficiency and good energy resolution needed down to very low energies (<100 MeV)

# Acceptance

$$e^+ e^- \rightarrow \text{hadrons}$$

$$e^+ e^- \rightarrow \text{hadrons}$$

Charged particle momentum distribution

## Event Rate

The cross-sections for the processes we wish to study vary over a significant range.

$$\sigma_{\mu\mu}(\sqrt{s} = 2 \text{ GeV}) = 21.7 \text{ nb}$$

$$\sigma_{had}(\sqrt{s} = 2 \text{ GeV}) \approx 43 \text{ nb} \quad (R = 2)$$

$$\sigma_{\bar{p}p} \approx \sigma_{\bar{n}n} \approx 1 \text{ nb}$$

Rates	$\mu\mu$	0.22 Hz
	had	0.43 Hz
	$p \bar{p}$	0.01 Hz
	$n \bar{n}$	0.01 Hz

Taking a maximum total cross-section of 100 nb and a maximum possible instantaneous luminosity of  $10^{31} \text{cm}^{-2} \text{s}^{-1}$ , the **maximum rate is 1 Hz**.

## Data Taking

Average instantaneous luminosity:  $5 \times 10^{30} \text{cm}^{-2} \text{s}^{-1}$   
( $\approx 0.5 \text{ pb}^{-1}/\text{day}$ )

### Measurement of R

Event Rate:  $\approx 0.25 \text{ Hz}$      $10000/\text{day}$   
(assuming a detection efficiency of 50 %).

i.e.  $1 \text{ point}/\text{day}$

assuming 200 points in 10 MeV intervals  
200 days data taking.

### Nucleon Form Factors

$\approx 200 \text{ events}/\text{day}$  (more than the total  
statistics of FENICE)

10 days/point

# Tracking

## Requirements:

- Good space resolution:  $\sigma = 200\div 300 \mu\text{m}$
- $dE/dx$  capability for particle ID
- low mass (to minimize multiple scattering)
- minimize dead spaces (frames, supports etc)

## TPC with slow He-based gas

(to minimize distortions due to magnetic field non-uniformity).

## Forward tracking:

- helps correct distortions in TPC
- veto for neutrons
- help with muon identification

## E.M. Calorimeter

### Requirements:

- high acceptance
- good efficiency and good energy resolution (few %) down to low energy (< 100 MeV)
- good time resolution

Lead and scintillating fibers calorimeter (à la KLOE).

### KLOE calorimeter

99 % efficiency for  $20 \text{ MeV} < E_\gamma < 500 \text{ MeV}$

$$\frac{\sigma(E)}{E} = \frac{5.7\%}{\sqrt{E(\text{GeV})}}$$

$$\sigma_z = \frac{1.24 \text{ cm}}{\sqrt{E(\text{GeV})}}$$

$$\sigma_t = \frac{54 \text{ ps}}{\sqrt{E(\text{GeV})}} + 110 \text{ ps}$$

## Particle I D

Particle identification is achieved by means of **two aerogel counters**, each 10 cm thick (total thickness 0.15 r.l.), which can achieve  **$4\sigma$   $\pi$ -K separation** in the momentum range **0.6÷1.5 GeV**.

**Below 0.6 GeV** particle I D will be based on **dE/dx** in the tracking chamber and on **TOF** in the forward EM calorimeter.

## Hadron Calorimeter

It is the main  $n$   $\bar{n}$  detector and thus it should:

- be efficient for neutrons
- allow antineutrons to interact
- provide TOF and position of both  $n$  and  $\bar{n}$ .

**The hadron calorimeter will be used also for muon I D.**

## Luminosity Measurement

### Online

Required for machine tuning and monitoring. **PEP-II** monitor, based on **single Bremsstrahlung at zero degrees**, seems appropriate.

### Offline

The necessary **1 % accuracy** in the integrated luminosity measurement can be achieved using **Bhabhas**.

**Muon pairs will be useful as a check.**

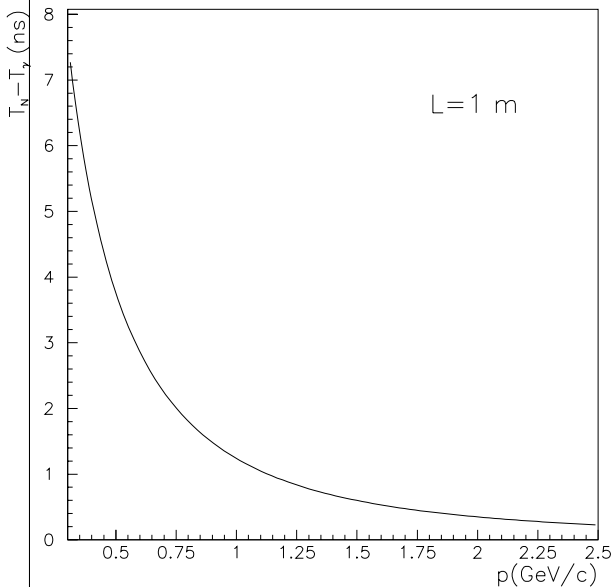

# N $\bar{N}$ I identification and measurement

- Angular Correlation

-good angular resolution  
-difficult at small  $E_{cm}$ .

- Time-of-flight to identify events and reject prompt photons and other fast backgrounds.

- Momentum analysis for  $\bar{p}p$
- Calorimetric measurement

# N $\bar{N}$ angular distribution

- $\theta_{\text{cm}}$  on an event by event basis.
- $\theta_{\text{cm}}$  from  $\theta_{\text{lab}}$  with two-fold ambiguity.
- tof for n  $\bar{n}$  and/or p for p  $\bar{p}$
- over-constrained fit with 2 particles
- fit to  $G_E/G_M$
- Example:
  - 5 m flight
  - 3 cm, 250 ps resolution
  - acceptance from  $1^\circ$  to  $45^\circ$
  - $G_E=0$

## N $\bar{N}$ detector requirements

- Angular coverage between  $1^\circ$  and  $40^\circ$  in polar angle.
- Detection of nucleons and antinucleons between 0.3 and 2.5 GeV/c with good efficiency.
- Momentum analysis for p and  $\bar{p}$ .

### Tracking device + Calorimeter

#### Tracking:

- measure p and  $\bar{p}$  direction and momenta.

#### Calorimeter:

- efficient for neutrons
- allow antineutrons to interact
- TOF and position of both n and  $\bar{n}$ .

Distance between detector face and interaction point: tof and angular resolution vs acceptance

# CONCLUSIONS

A detector layout has been presented suitable for the measurement of  $R$ , of exclusive hadronic final states and of nucleon form factors.

The various detector components are being studied in detail and will be presented in dedicated talks.

The overall performances of the detector are being studied by means of Monte Carlo Simulation, whose results will also be shown in the dedicated talk.
